**Short communication**

*Sordaria fimicola* (Ascomycota, Sordariales) on *Acer palmatum*

Helena Ivanová

Institute of Forest Ecology of the Slovak Academy of Sciences, Branch for Woody Plants Biology, Akademická 2, 949 01 Nitra, Slovak Republic, e-mail: helena.ivanova@savzv.sk

**Abstract**

During an investigation of the mycoflora of Japanese red maple trees growing in an urbanized area of Nitra, Slovakia, *Sordaria fimicola* (Roberge ex Desm.) Ces. & De Not) was isolated from affected leaves and branches of *Acer palmatum* ´Atropurpureum´ L. This fungus was associated with symptoms of brown wood discoloration and leaf spottness of these trees. *Sordaria fimicola* was recorded for the first time on *Acer palmatum* ´Atropurpureum´ in Slovakia. The fungus is characterized by dark brown ascomata clothed with setae, fasciculate, unilicate, cylindrical asci, and olivaceous to olivaceous-brown, one-celled, ellipsoidal, smooth-walled ascospores with a colourless basal germ pore and surrounded by a gelatinous sheath.

**Keywords**

ascomycetes, Japanese red maple, pathogenic fungus

**Introduction**

In recent years stems and branches of woody hosts such as fruit and ornamental trees have been shown to share the same range of fungi, which are able to migrate between these different hosts (Mostert et al., 2005, 2006; Essakh et al., 2008). However, most of these genera are typical inhabitants of wood and bark, occurring on a broad spectrum of trees and shrubs worldwide (Schoch et al., 2009; Zhang et al., 2009).

These fungi associated with symptoms of brown wood discoloration and leaf spottness include several ascomycetes such as *Sordaria*. Several members of this order have been isolated from remains of plant biomass, live plants, from seeds and from soil (Lundqvist, 1972; Doveri, 2004; Richardson, 2008) and they are important candidates for studies in genetics and biochemistry (Kendrick, 2000). Natural habitat of this species is dung of herbivorous animals (Fields, 1970).

The aim of this work was to isolate and identify the organism occurring on infected Japanese red maple leaves and branches in green areas of Nitra.

**Material and methods**

The samples of leaves and twigs of *Acer palmatum* ´Atropurpureum´ showing blight symptoms were gathered from plants growing in private gardens of the town Nitra, during summer–autumn 2013 and summer 2014. Altogether 15 trees were studied. The age of evaluated trees was between 5–10 years. The collected material was deposed in herbarium at the Institute of Forest Ecology of the Slovak Academy of Sciences, Branch for Woody Plant Biology in Nitra. *Sordaria fimicola, Acer palmatum* ´Atropurpureum´, Slovakia, Nitra, Zobor-hill, 2. July 2013, leg. H. Ivanová (IFE SAS, Nitra, Slovakia, NR 5190). Pure cultures were obtained through cultivation on nutritive 3% PDA medium in a test chamber with constant temperature and humidity (24 ± 1 °C and 45% humidity in dark conditions in a versatile environmental test chamber MLR-351H – Sanyo). Leaves and twigs cut from the diseased plants were surface-sterilized for 20 minutes. Study of fungal structures was performed with a light clinical microscope BX41 (Olympus) under 400× and 1,000×.
magnification. Measurements were made using Quick-Photomicro 2.2 programme and the morphometric values were compared with previously published data for the taxa (Lundquist, 1972; Alexopoulos et al., 1996; Crous et al., 2009).

Results and discussion

Many fungal diseases cause damage to ornamental tree species in the genus Acer, including Acer palma-tum ‘Atropurpureum’. Among pathogenic fungi, microscopic pathogens isolated and identified from the affected leaf and branch tissues include ascomycetous fungi in the genus Sordaria. The causal organism – Sordaria fimicola (Roberge) Ces. & De Not., (syn. Sphaeria fimicola Roberge in Desm.) (Sordariomycetes, Ascomycota) was systematically isolated from the leaf and twig tissues showing rusty to brown coloured blight symptoms. Microscopic examination of fresh material indicated that the ascomycete fungus from Slovakia fits well within the genus Sordaria. Thick-walled, obpyriform, densely aggregated ascomata, as well as olivaceous, dark brown ascospores at maturity with a basal germ pore suggest this fungus is Sordaria fimicola on Acer palmatum ‘Atropurpureum’.

White at the beginning homothallic colonies fast growing on PDA (Fig. 1a) formed sparse aerial mycelium pale white colour. Dark, mostly densely aggregated superficial, obpyriform pycnidia were formed after 1 week of inoculation in dark conditions (Fig. 1b). Vegetative hyphae were thin-walled, septate, branched (Fig. 1c), lacking chlamydospores. Macroconidia did not discover. The ascomata were superficial, glabrous or sparsely covered with flexuous, colourless hairs (Fig. 1d), pear-shaped or obpyriform, with central ostiole (Fig. 1e). The ascosporas walls were thick, composed of several layers, on the outer surface with hyaline, straight or bent short setae 80–100 × 6 μm in size, sometimes shorter. Paraphyses absent, periphyses lining the ostiole. Asci (Figs 1f, g) with eight uniseriate ascospores on ascus arranged obliquely and formed rosettes (Figs 1h, i), growing from the bottom of the peritheium. Ascospores were olivaceous to olivaceous-brown, aseptate with a colourless basal germ pore (Fig. 1j), immature were granular (Fig. 1k), mature ascospores (Fig. 1m) were brown and ellipsoidal to obovoid.

According to Alexopoulos et al. (1996) and García et al. (2004) species are characterized by black globose or flask-shaped solitary perithecia, which are ostiolate, usually with stiff setae, forming cylindrical asci with an apical ring. The ascus apex usually has one or several germ pores and a refractive ring through which the ascospores are discharged. Sordaria species have smooth-walled, dark brown ascospores, generally aseptate, with the surface smooth, pitted, reticulate or striate, sheathed or unsheathed. Spores surrounded gelatinous sheath which is sometimes thick and conspicuous, or it is difficult to detect. Darkly pigmented ascospores show wide variation in the kinds of appendages or sheaths. (Important aspect of the life cycle of this species is that no macroconidia are formed). Microconidia are produced, functioning as male gametes in sexual reproduction. Germination of microconidia may occur, but it is very poor.

When compared morphologically with the species occurring on different trees reported in the literature (Lundquist, 1972; Doveri, 2004), Sordaria fimicola differs from S. macrospora in having smaller spores, ellipsoidal rather than broadly ellipsoidal and smaller perithecia and asci (Crous et al., 2009). Comparison of the main morphological characteristics of S. fimicola identified on different hosts and examined material is described in Table 1.

Up to now, fungus Fusarium sp. has been known as an opportunistic and quite common pathogen associated with infected Japanese red maple leaves and branches. This fungus, which caused Fusarium wilt disease, remains in infested soils for up to ten year. Wilt may be contracted through infected seed, plant debris or soil. The fungus begins and multiplies during the cool, moist season, becoming obvious when weather turns warm and dry. Plants wilt because the fungus damages their water conducting mechanisms (Ivanová, 2013). Important finding is that S. fimicola was identified for the first time as a new pathogenic fungus associated with infected Acer palmatum ‘Atropurpureum’ in Slovakia. Further studies are required for determination of pathogenicity and relevance of Sordaria infection in connection with Japanese red maple tree damage.

Acknowledgement

I thank Dr. Emília Ondrušková for helping with identification of fungal species. This study was conducted thanks to financial support from the Ministry of Education of the Slovak Republic for project No. 2/0071/14.

**Ascomata**
- Green to brown, one-celled, elipsoid, smooth-walled, with a truncate apex and small apical ring, 8-spored, 111–163 × 10.5–14 μm, cylindrical, flattened at apex, short stipitate, with a lobate stipe and prominent apical apparatus.
- Green to brown, one-celled, elipsoid, smooth-walled, with a truncate apex and small apical ring, 8-spored, 111–163 × 10.5–14 μm, cylindrical, flattened at apex, short stipitate, with a lobate stipe and prominent apical apparatus.
- Green to brown, one-celled, elipsoid, smooth-walled, with a truncate apex and small apical ring, 8-spored, 111–163 × 10.5–14 μm, cylindrical, flattened at apex, short stipitate, with a lobate stipe and prominent apical apparatus.

**Asci**
- 150 (165) × 15 μm, fasciculate, uniseriate, cylindrical, with a truncate apex and small apical ring, 8-spored, (155–) 170–215 × 14–17 μm, with a truncate 9 μm apex.
- 150 (165) × 15 μm, fasciculate, uniseriate, cylindrical, with a truncate apex and small apical ring, 8-spored, (155–) 170–215 × 14–17 μm, with a truncate 9 μm apex.
- 150 (165) × 15 μm, fasciculate, uniseriate, cylindrical, with a truncate apex and small apical ring, 8-spored, (155–) 170–215 × 14–17 μm, with a truncate 9 μm apex.

**Ascospores**
- Aseptate, binucleate, at maturity dark brown, ellipsoidal to obovoid (17–) 18–24 × (9.5–)10–13 µm, often slightly inequilateral, rounded above, somewhat apiculate below with a basal germ pore, gelatinous sheath surrounding the spore except for a basal invagination.
- Aseptate, binucleate, at maturity dark brown, ellipsoidal to obovoid (17–) 18–24 × (9.5–)10–13 µm, often slightly inequilateral, rounded above, somewhat apiculate below with a basal germ pore, gelatinous sheath surrounding the spore except for a basal invagination.
